Bluetooth Asia 2019

Agenda

1

Bluetooth multi-link concepts and implementations

2

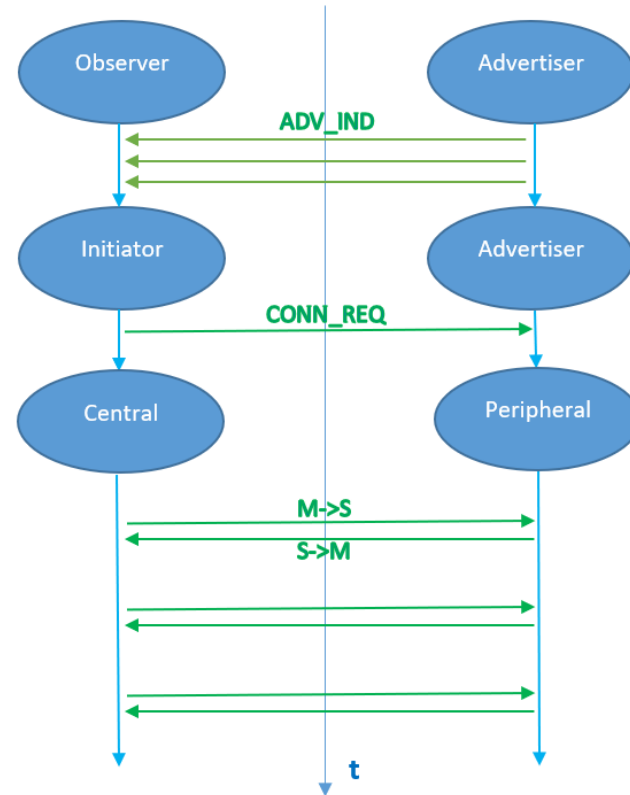

True low power relay network and mesh design

3

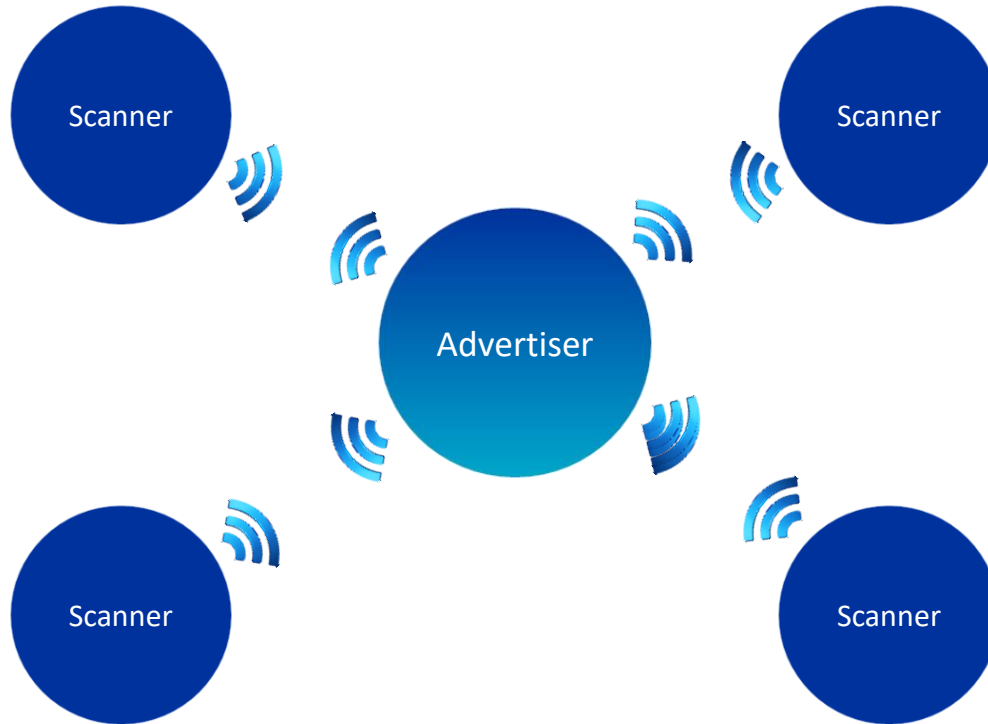

Bluetooth multi-link use case study

LE roles

- Advertiser/Broadcaster
- Observer/scanner
- Initiator
- Master/central
- Slave/peripheral

LE topology – Broadcast

LE topology – Connection/Link

Bluetooth connection evolution

Single link peripheral

2011

Peripheral / multi-link
master

Up to 8 links

Concurrent peripheral /
multi-link central

Up to 8 links

Concurrent multi-link
peripheral and central

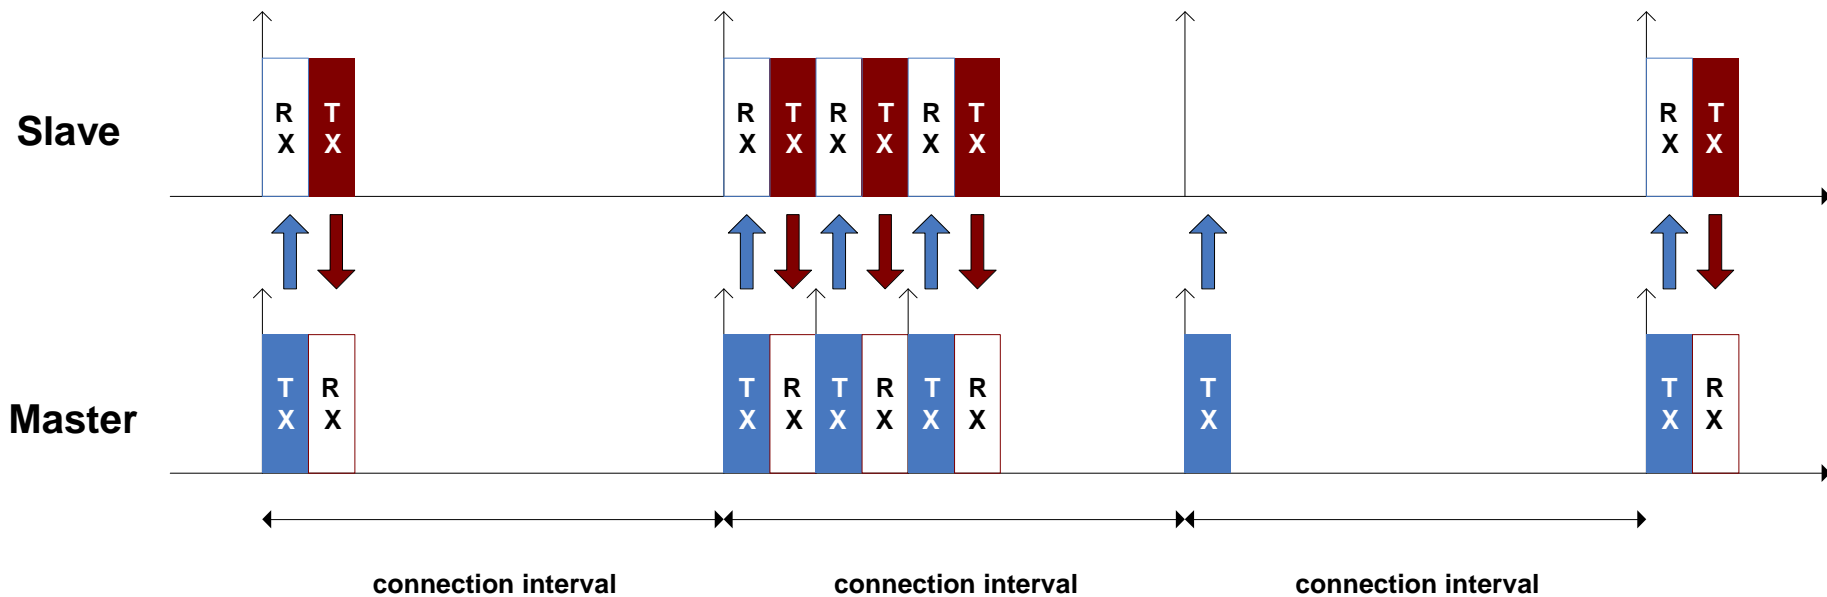

Up to 20 links

Today

Advertising/Scanning timing

1-Link connection timing

Multi-Link connection timing

Challenges for multilink implementation

- Fast radio startup and switch
- Good scheduling
- Accurate time slot
- Robustness
- Flexibility
- Nice and clean SDK
- ...

Radio working timing

Radio performance

Fast radio
startup

Fast radio
switch

Fast
execution

Radio
Active

Idle w/ RTC

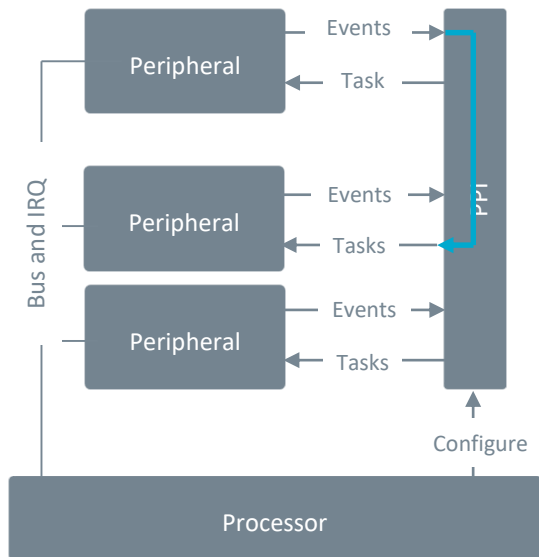

Demanding Time requirement

$t_1/t_2/t_3$: connection interval

t_4/t_5 : inter-link time

PPI-Programmable Peripheral Interconnect

Autonomous Peripheral Interaction

Complements Regular Interrupts

Independent Operation

Configurable Task – Events Mapping

Offload CPU

Power Saving

Real-time Operation

PPI channels in Bluetooth protocol stack (Softdevice)

Channel	EEP	TEP
20	TIMER0->EVENTS_COMPARE[0]	RADIO->TASKS_TXEN
21	TIMER0->EVENTS_COMPARE[0]	RADIO->TASKS_RXEN
22	TIMER0->EVENTS_COMPARE[1]	RADIO->TASKS_DISABLE
23	RADIO->EVENTS_BCMATCH	AAR->TASKS_START
24	RADIO->EVENTS_READY	CCM->TASKS_KSGEN
25	RADIO->EVENTS_ADDRESS	CCM->TASKS_CRYPT
26	RADIO->EVENTS_ADDRESS	TIMER0->TASKS_CAPTURE[1]
27	RADIO->EVENTS_END	TIMER0->TASKS_CAPTURE[2]
28	RTC0->EVENTS_COMPARE[0]	RADIO->TASKS_TXEN
29	RTC0->EVENTS_COMPARE[0]	RADIO->TASKS_RXEN
30	RTC0->EVENTS_COMPARE[0]	TIMER0->TASKS_CLEAR
31	RTC0->EVENTS_COMPARE[0]	TIMER0->TASKS_START

Scheduling timing-activities

- Only 1 radio peripheral
- Different timing-activities/events
 - Central role timing-activities
 - Peripheral role timing-activities
 - Advertiser timing-activities
 - Scanner/Initiator timing-activities
 - Flash Access timing-activities
 - Radio time-slot timing-activities
 - QoS channel survey timing-activities

Scheduling principles

- Advertiser and broadcaster timing-events are scheduled as early as possible
- Peripheral link timing-events follow the timings dictated by the connected peer
- Central link timing-events are added relative to already running central link timing-events, close to each other (without any free time between them)
- If timing-events collide, their scheduling is determined by a priority system

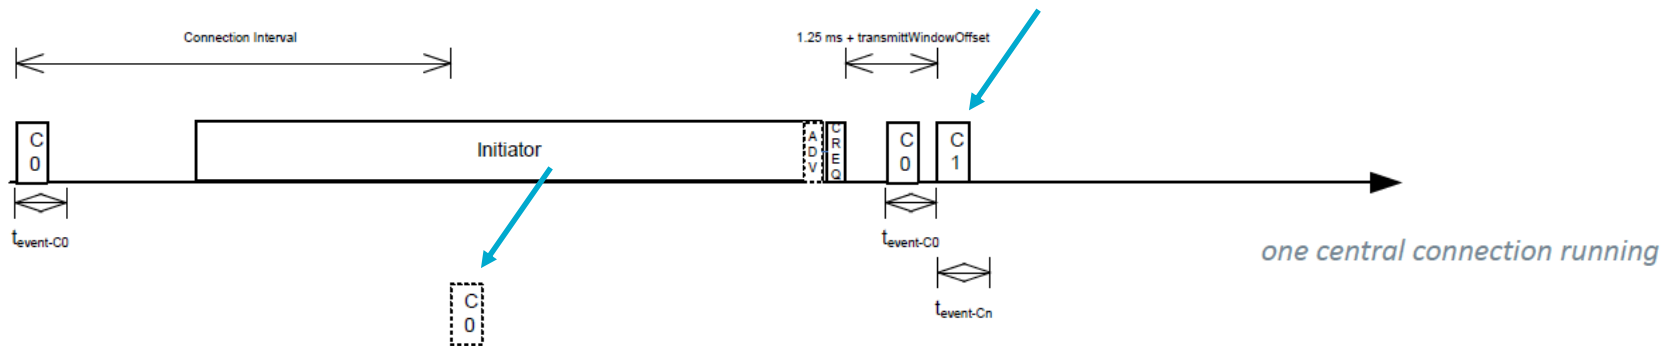

Priority

Priority (Decreasing order)	Role state
First priority	<ul style="list-style-type: none"> • Central connections that are about to time out • Peripheral connection setup (waiting for ack from peer) • Peripheral connections that are about to time out
Second priority	<ul style="list-style-type: none"> • Central connection setup (waiting for ack from peer) • Initiator • Connectable advertiser/Broadcaster/Scanner which has been blocked consecutively for a few times
Third priority	<ul style="list-style-type: none"> • All <i>Bluetooth</i> low energy roles in states other than above run with this priority • Flash access after it has been blocked consecutively for a few times • Radio Timeslot with high priority
Fourth priority	<ul style="list-style-type: none"> • Flash access • Radio Timeslot with normal priority
Last priority	<ul style="list-style-type: none"> • QoS channel survey

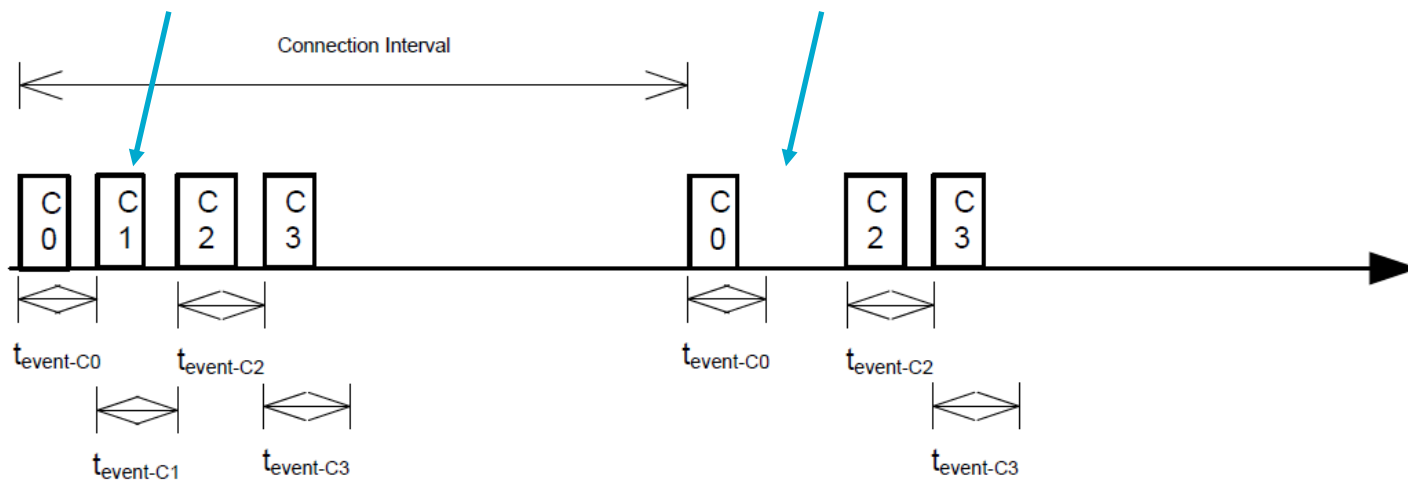

Scheduling priorities

- Higher priority timing-activity get the timing-event if overlapped by lower priority timing-activity
- First come first served for the same priority timing-activities
- Once started the timing-event cannot be preempted by any other timing-activities
- The different timing-activities have different priorities at different times, dependent upon their states

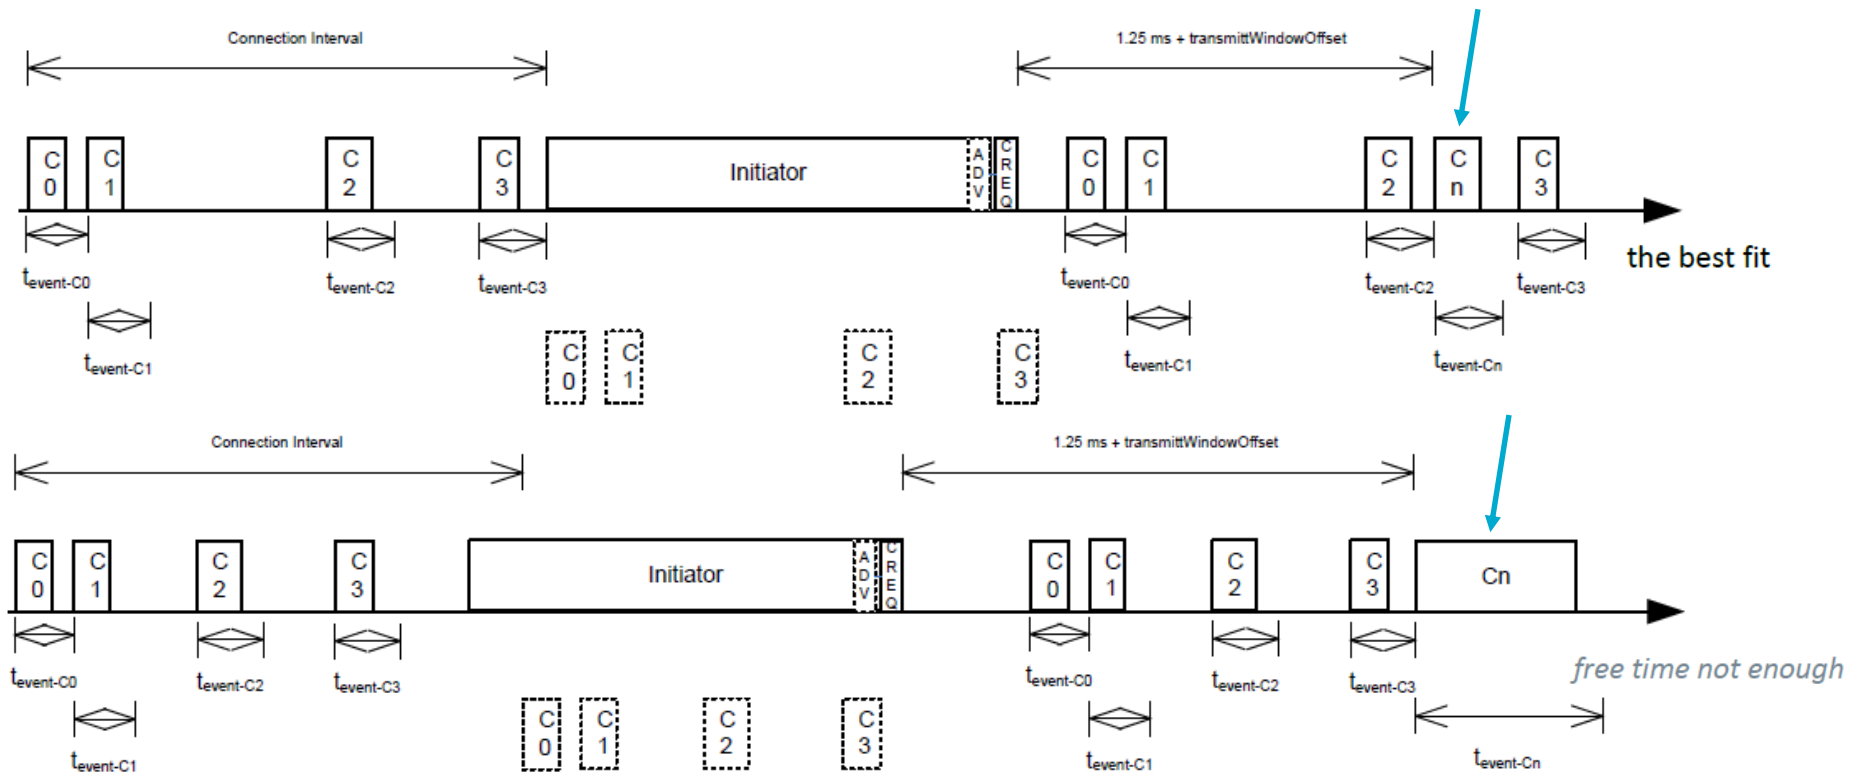

Initiator timing 1

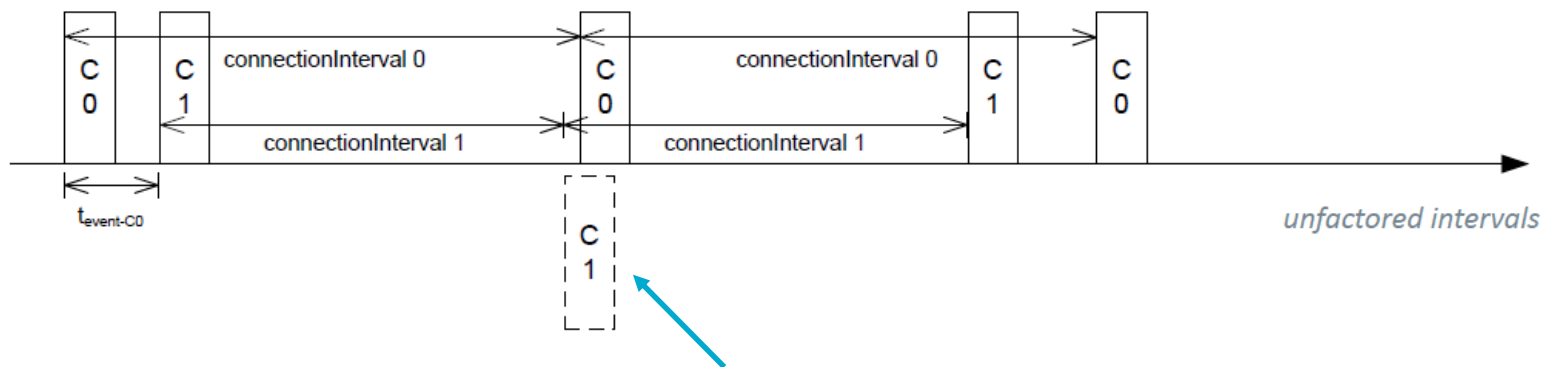

Disconnection

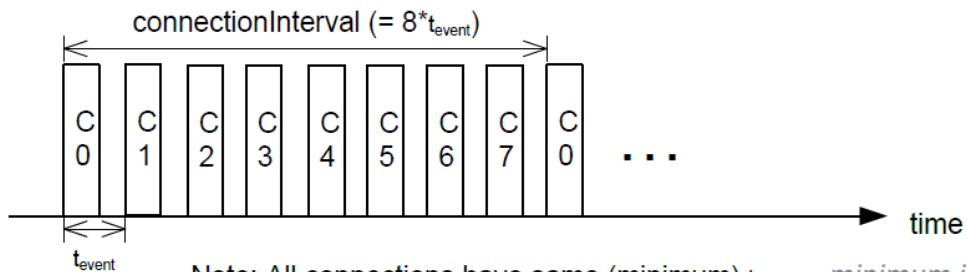

Initiator timing 2

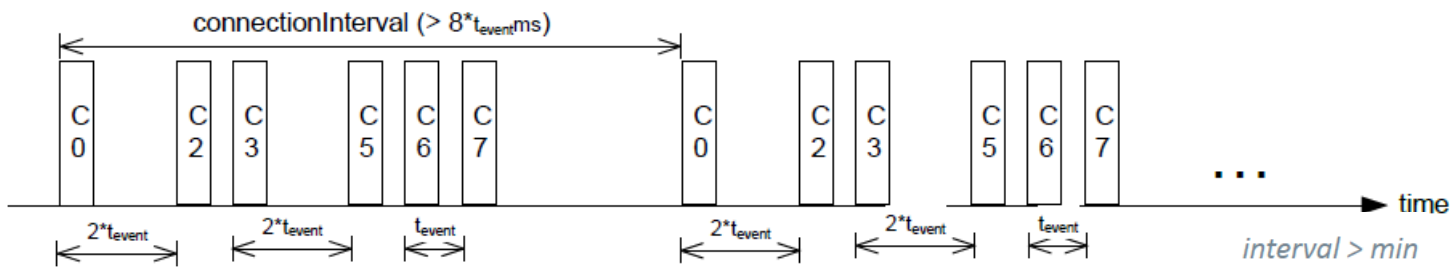

Central connection timing 1

Central connection timing 2

Note: All connections have same (minimum) t_{event} *minimum interval*

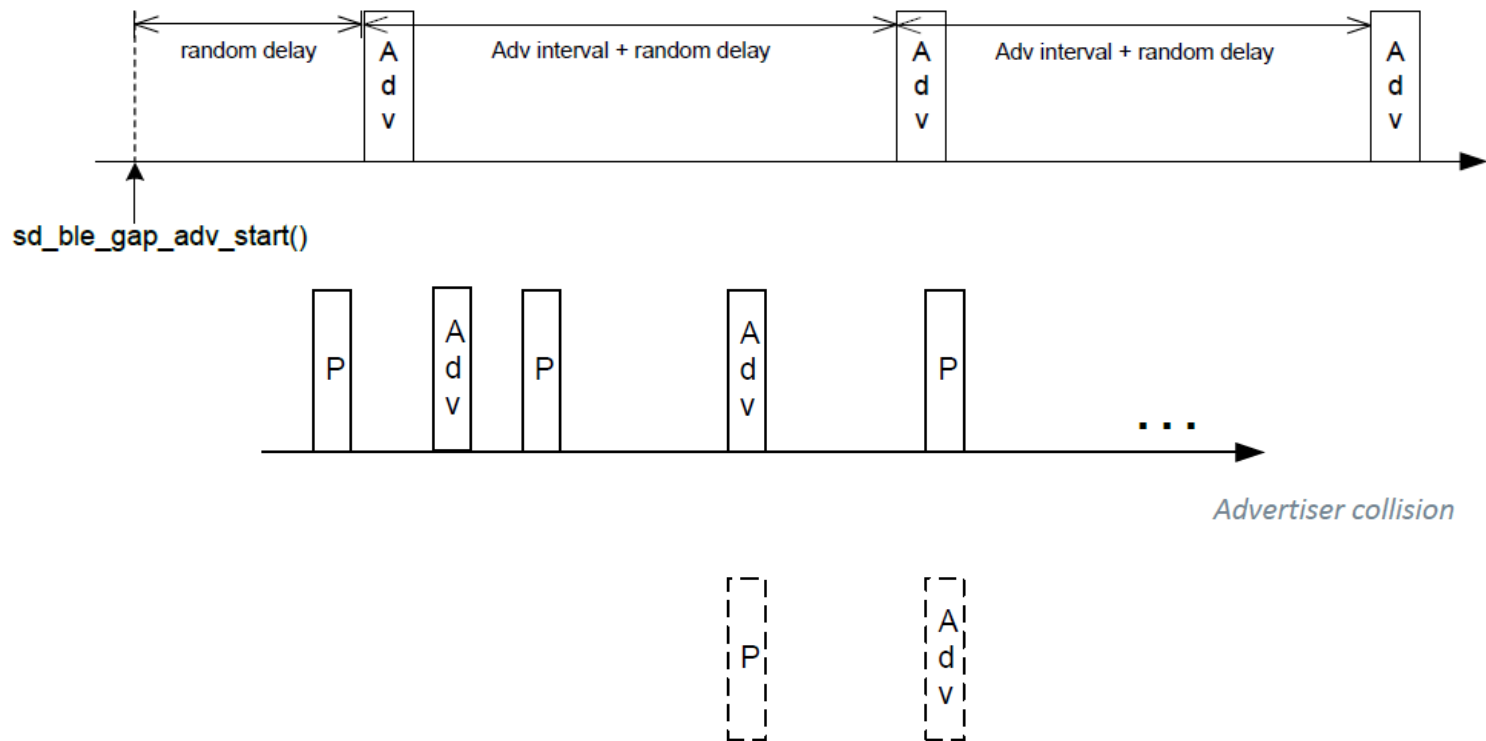

Note: All connections have same (minimum) t_{event}

Scanner timing

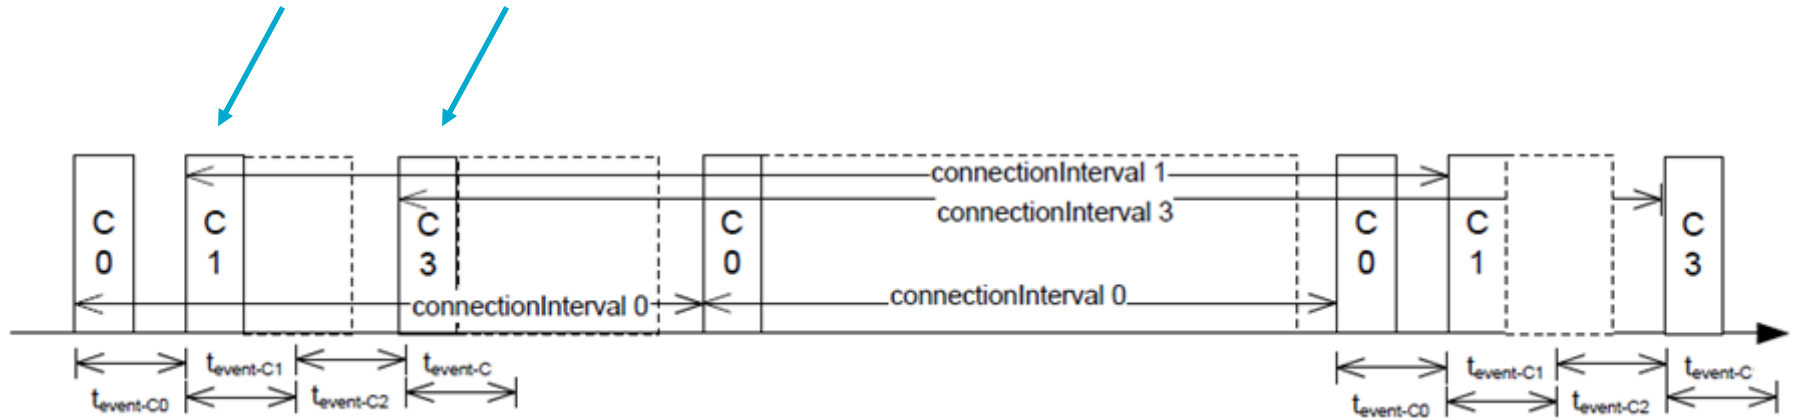

Advertiser timing

Peripheral connection timing

Connection event length extension

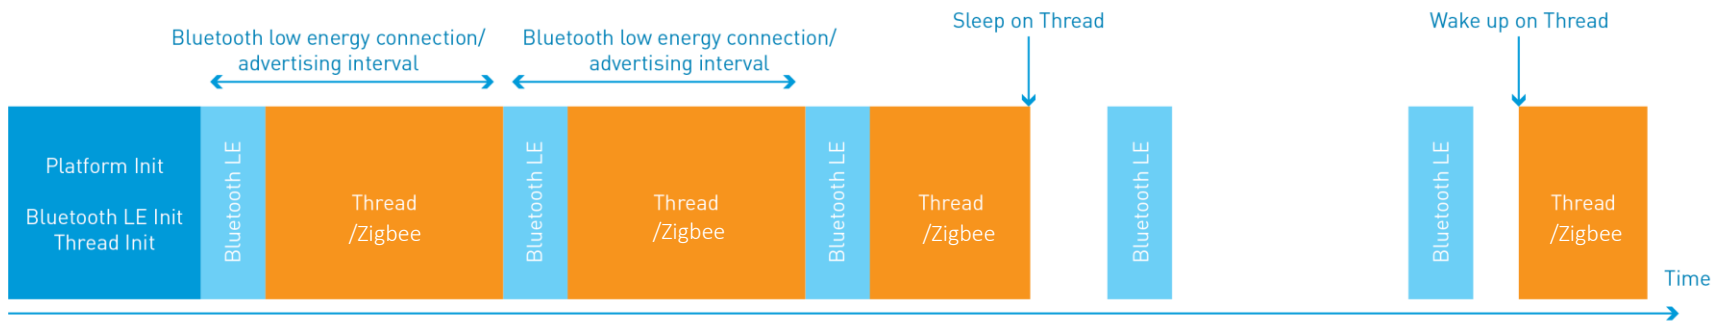

Suggested intervals and windows

- Interval of all roles have a common factor which is $\geq \Sigma t_{\text{event-Cx}} + (t_{\text{ScanReserved}} + \text{ScanWindow}) + t_{\text{SlaveEventNominal}} + t_{\text{AdvEventMax}}$
- When long Link Layer Data Channel PDUs are in use, it is recommended to increase the event length of a connection
- A recommended configuration for having fewer colliding Peripherals is to set a short event length and enable the Connection Event Length Extension in the SoftDevice
- Set the supervision time-out for connections long enough to avoid loss of connection when packets are dropped

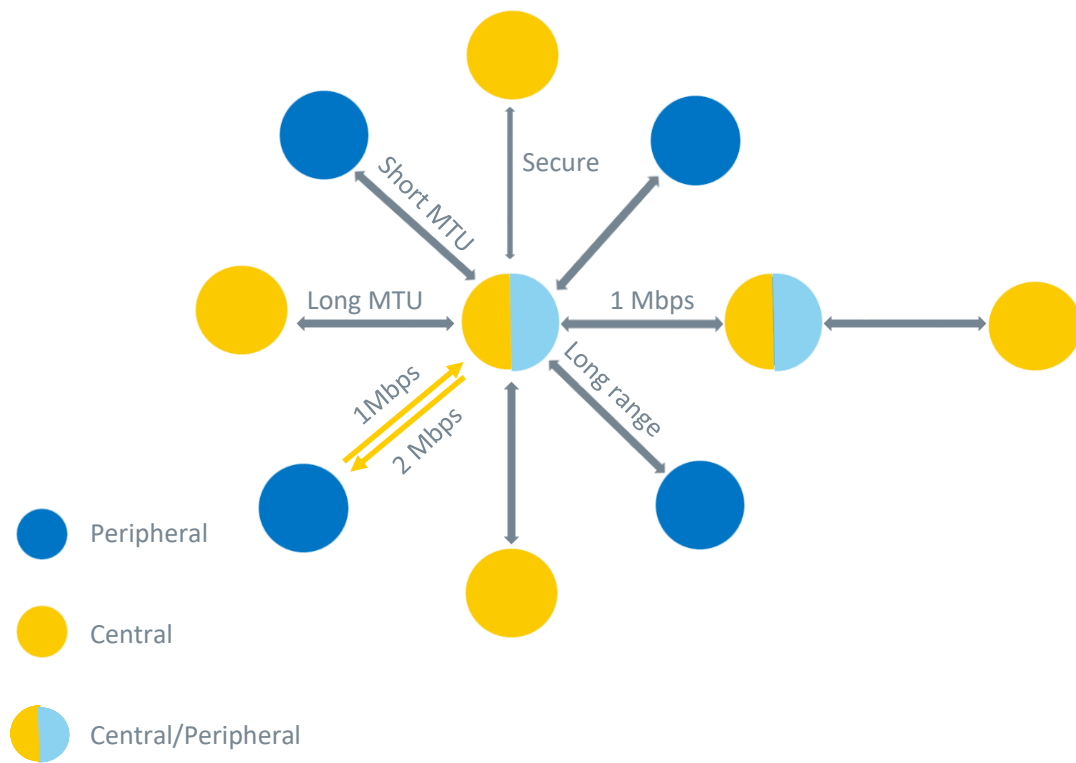

Time-slot API

- Multilink connotation can extend to Zigbee/Thread/2.4G
- Time slot API is used to multiplex radio resource
- Time slot is a part of softdevice scheduling mentioned previously
- Concurrent LE and Zigbee/Thread/2.4G

Concurrent LE and other protocols

Flexible Bluetooth Multilink

- Concurrent master and slave
- Concurrent client and server
- Configurable MTU for each link
- Configurable PHY for each link
- Secure the link or not
- Up to 20 active links

Easy to use

- Complicated multilink doesn't mean complicated SDK
- To start a new advertising or a new peripheral link, call **sd_ble_gap_adv_start** no matter how many running links are
- To start a new scanning or a new central link, call **sd_ble_gap_scan_start** no matter how many links are running
- That's it. Let softdevice handle the rest for you!

Agenda

1 **Bluetooth multi-link concepts and implementations**

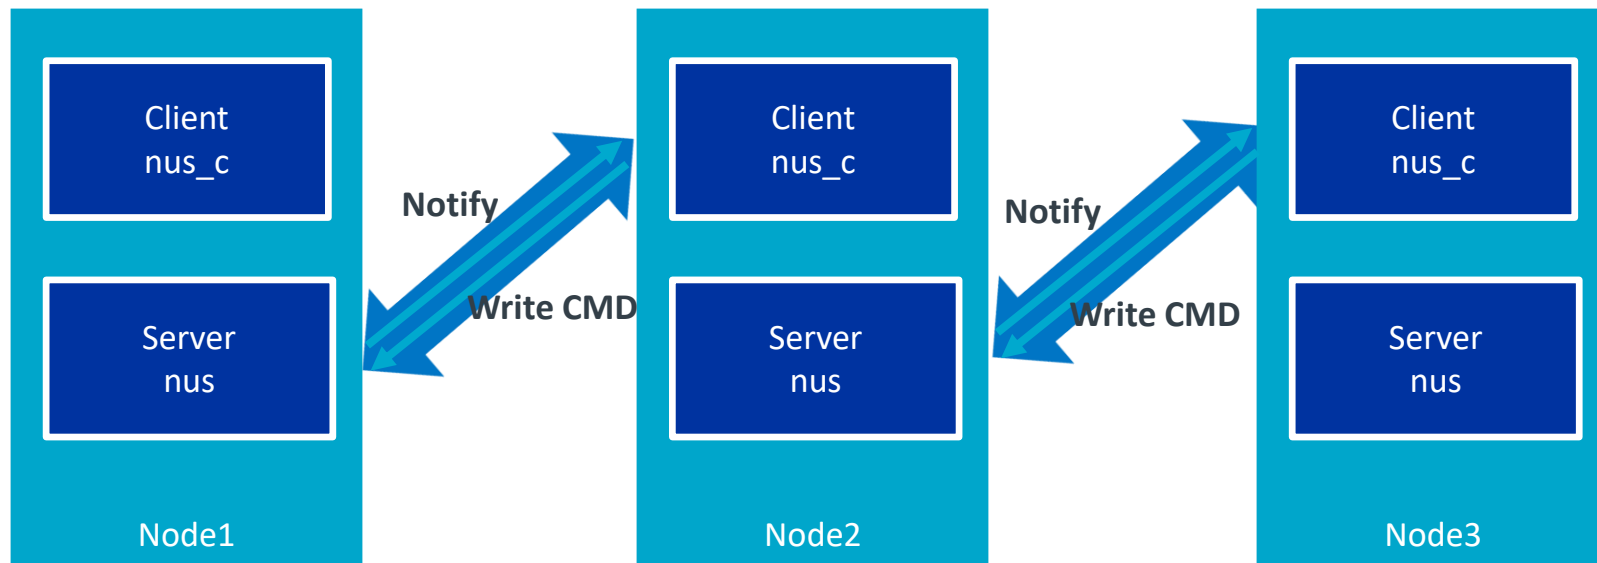

2 **True low power relay network and mesh design**

3 **Bluetooth multi-link use case study**

Challenges when building a relay network by Bluetooth multilink

- All the nodes have the same firmware
- Master/Slave asymmetry
- Client/Server asymmetry
- One link for one pair
- Determined roles for the specific link

ATT transparent communication (NUS)

Interactive API abstraction

- Server -> Client, `sd_ble_gatts_hvx(conn_handle, &hvx_params);`
- Client -> Server, `sd_ble_gattc_write(conn_handle, &write_params);`
- `conn_handle`, connection handle, to identify a link
- `nus_send(conn_handle, p_data, length)`
- Be aware that server can send/receive data to/from client, client can send/receive data to/from server as well. The difference between them is who is the owner to build ATT database

Relay topology

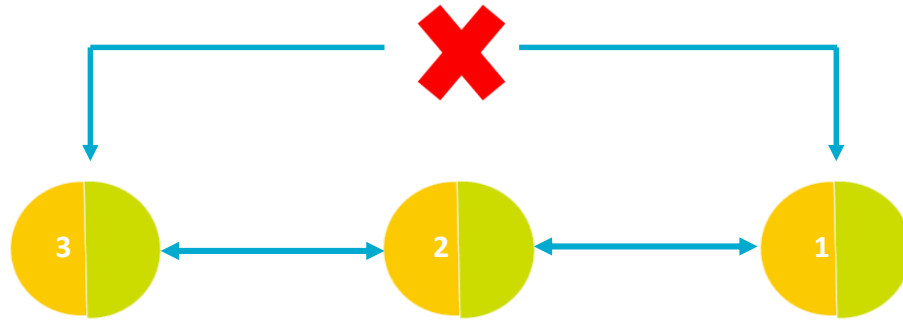

Challenges upgrading relay to mesh

- Select a provisioner – first master device
- Assign an unique address for each node – provisioner coordinate
- Distinguish provisioned device and un-provisioned device – advertising name
- Routing or reconnection – name and device address filter
- Recover – name filter and authentication data persistent

Building a GATT mesh example 1

- 2 central link 1 peripheral link
- Use NUS and NUS_C for GATT interaction
- Use HRS_c for secure link
- Input command by UART
- Print logs by RTT

Building a GATT mesh example 2

The Mesh example topology

Node2 power consumption

GATT mesh advantages

- All low power nodes
- Specified 'physical' routing
- Fast setup
- Best of class security. Each link is secured separately
- Easy to use and deploy
- Compatible with other LE apps

Agenda

1 **Bluetooth multi-link concepts and implementations**

2 **True low power relay network and mesh design**

3 **Bluetooth multi-link use case study**

ESL AP

- Advertising/Peripheral.
Interact with ESL
- Scanning/Central.
Discover other devices

Smart door lock

- Peripheral for configuration and unlocking
- Central for unlocking
- Concurrent Zigbee to interact with smart home system

Smart power meter

- Master role connecting to breakers
- Slave role connecting to phone or aggregator

Smart Bus Display

- 4 screens or more are interconnected
- 4 master link 1 slave link
- or GATT Mesh

Night light relay

- Bluetooth multilink relay network
- Phone configuration
- Low power

蓝牙多连接，释放无限想象

- 构建基于GATT的全网低功耗节点的私有Mesh
